

Decision Tree Classifier

(Introduction, ID3 Algorithm)

Dr. JASMEET SINGH
ASSISTANT PROFESSOR, CSED
TIET, PATIALA

Decision Tree Classifier - Introduction

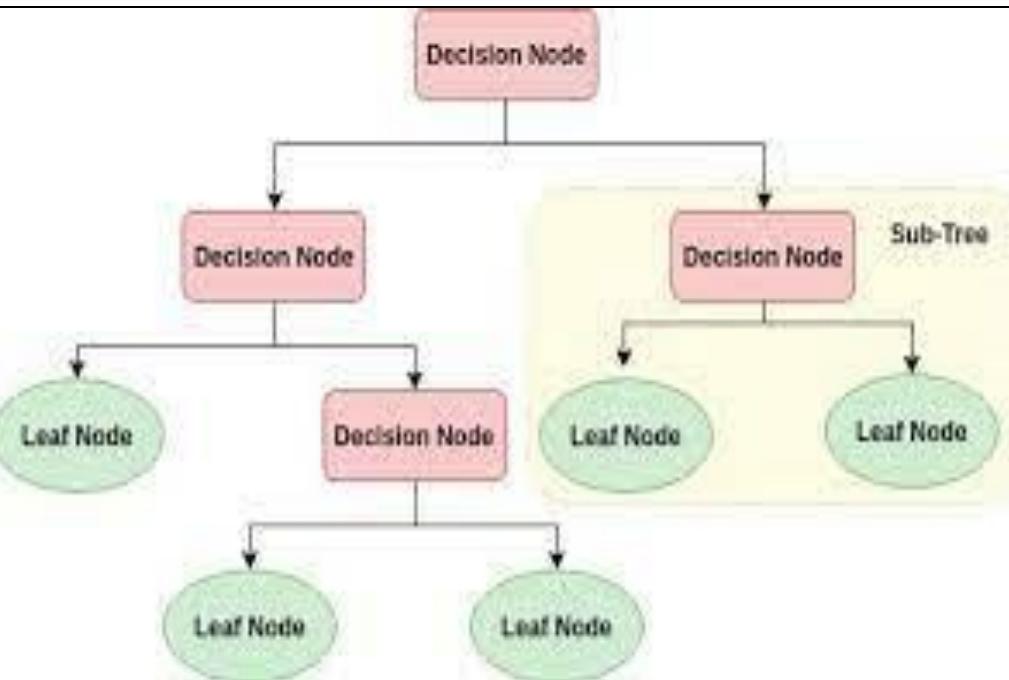

- Decision Tree Classifier is a supervised learning algorithm
- It is a distribution-free or non-parametric method, which does not depend upon probability distribution assumptions.
- Decision trees are one of the most important concepts in modern machine learning.
- Not only are they an effective approach for classification and regression problems, but they are also the building block for more sophisticated algorithms like random forests and gradient boosting.

Decision Tree Classifier - Introduction

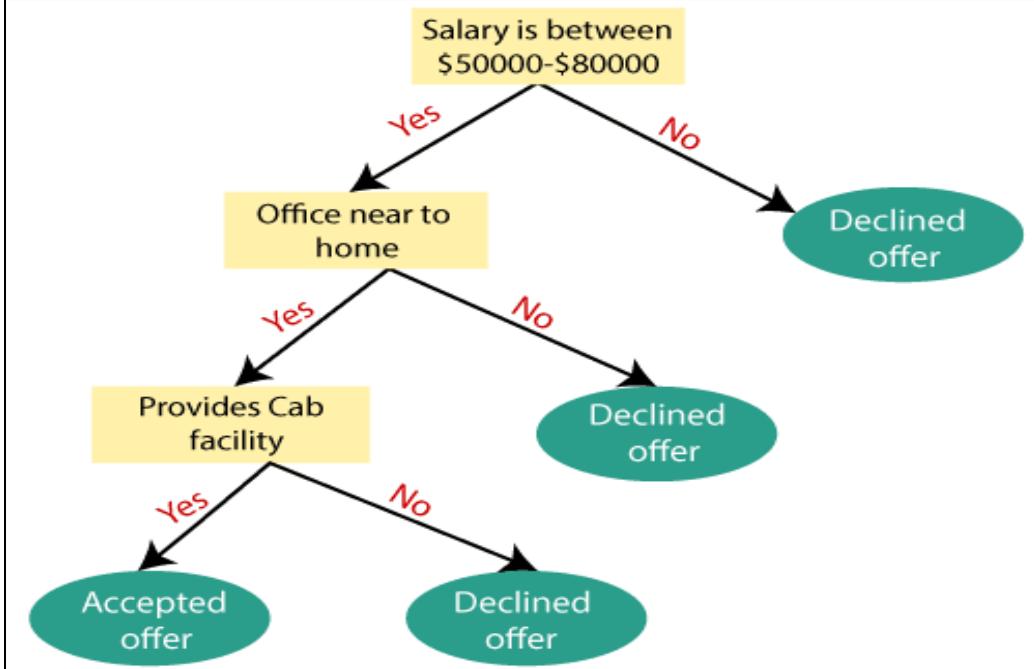

- Decision trees can handle high dimensional data with good accuracy by constructing internal decision-making logic in a form of a decision tree.
- A decision tree is a flowchart-like tree structure where
 - an internal node represents feature(or attribute)-represented as square,
 - the branch represents a decision rule,
 - and each leaf node represents the outcome- represented as ovals.
- Conceptually, decision trees are quite simple. We split a dataset into smaller and smaller groups, attempting to make each one as “pure” or “homogenous” as possible.
- Once we finish splitting, we use the final groups to make predictions on unseen data.

Decision Tree Classifier - Introduction

GENERAL DECISION TREE STRUCTURE

DECISION TREE- THAT ACCEPTS OR REJECTS A JOB OFFER ON THE BASIS OF SALARY, DISTANCE AND CAB FACILITY

Variants of Decision Tree Classifier

- A successful decision tree is one that does a good job of “splitting” data into homogeneous groups.
- Therefore, in order to build a good decision tree algorithm, we’ll need a method for evaluating splits.
- There are several different different algorithm used to generate trees such as,
- **ID3**
 - Uses information gain, to decide the partition feature,
 - not designed to deal with continuous features
- **CART** (Classification and regression trees)
 - Uses Gini coefficient to decide partition feature
- **C4.5**
 - Works similar to ID3 by using information gain to split data.
 - However C4.5 can handle continuous features, as well as can work with missing data

ID3 (Iterative Dichotomiser 3) Algorithm

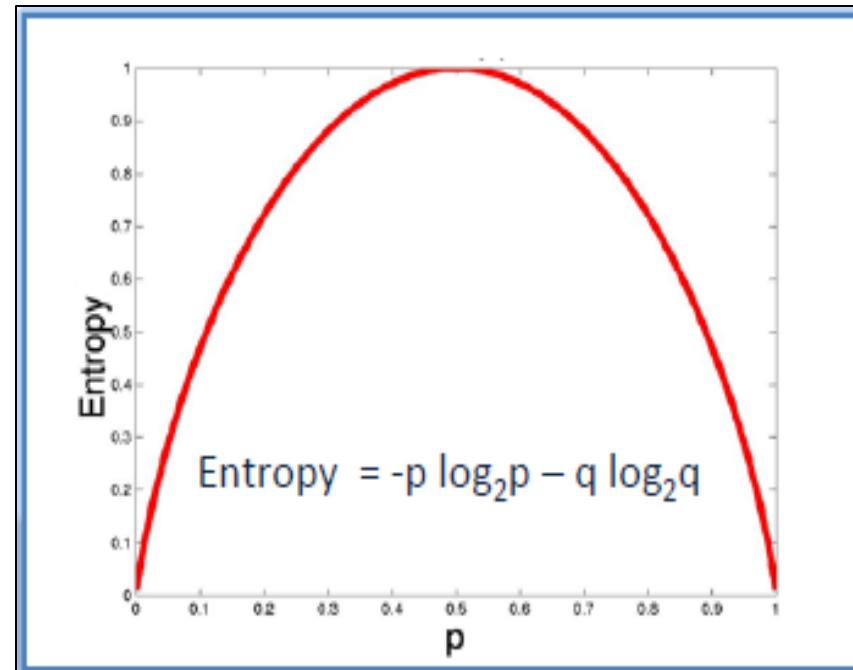

- ID3 stands for *Iterative Dichotomiser 3* and is named such because the algorithm iteratively (repeatedly) dichotomizes(divides) features into two or more groups at each step.
- Invented by Ross Quinlan, ID3 uses a **top-down greedy** approach to build a decision tree.
- In simple words, the **top-down** approach means that we start building the tree from the top and the **greedy** approach means that at each iteration we select the best feature at the present moment to create a node.

ID3 (Iterative Dichotomiser 3) Algorithm

- ID3 generates a tree by considering the whole set S as the root node.
- It then iterates on every attribute and splits the data into fragments known as subsets to calculate the entropy or the information gain of that attribute.
- After splitting, the algorithm recourse on every subset by taking those attributes which were not taken before into the iterated ones.
- The best feature in ID3 is selected using *Entropy and Information Gain* metrics.

Entropy

- It is defined as a measure of impurity present in the data.
- Entropy calculates the homogeneity of a sample.
- If the sample is completely homogeneous the entropy is zero and if the sample is equally divided it has entropy of one (as shown in figure for binary classes).
- Entropy with the lowest value makes a model better in terms of prediction as it segregates the classes better.

$$\text{Entropy} = -0.5 \log_2 0.5 - 0.5 \log_2 0.5 = 1$$

Entropy (Contd....)

- Entropy of dataset (S) is computed as follows:

$$Entropy(S) = - \sum_{i=1}^n p_i \log_2(p_i)$$

Where n is the total number of classes in the target column (in our case n = 2 i.e YES and NO)

p_i is the **probability of class ‘i’** or the ratio of “*number of rows with class i in the target column*” to the “*total number of rows*” in the dataset.

Information Gain

- In a decision tree building process, two important decisions are to be made
 - what is the best split(s)
 - and which is the best variable to split a node.
- Information Gain criteria helps in making these decisions.
- We need to calculate Entropy of Parent and Child Nodes for calculating the information gain due to the split.
- The concept of Information Gain is based on:

The more we know about a topic, the less new information you are apt to get about it. To be more concise: If you know an event is very probable, it is no surprise when it happens, that is, it gives us little information that it actually happened.

- The amount of information gained is inversely proportional to the probability of an event happening.
- We can also say that as the Entropy increases the information gain decreases. This is because Entropy refers to the probability of an event.

Information Gain (Contd...)

- Information Gain = Entropy of Parent - sum (weighted % * Entropy of Child)
Weighted % = Number of observations in particular child/sum (observations in all child nodes)

- In particular, Information Gain for a feature column **A** is calculated as:

$$\text{Information Gain}(S, A) = \text{Entropy}(S) - \sum_{v=1}^{|v|} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$$

where S_v is the set of rows in S for which the feature column **A** has value v , $|S_v|$ is the number of rows in S_v and likewise $|S|$ is the number of rows in S .

- **Information Gain calculates the reduction in the entropy and measures how well a given feature separates or classifies the target classes.**
- **The feature with the highest Information Gain is selected as the best one.**

ID3 Algorithm-Pseudocode

- **ID3(*instances*, *target_attribute*, *attributes*)**
 - Create a new *root* node to the tree.
 - **If** all instances have the *target_attribute* belonging to the same class *c*,
 - **Return** the tree with single *root* node with label *c*.
 - **If** *attributes* is empty, then
 - **Return** the tree with single *root* node with the most common label of the *target_attribute* in *instances*.
 - **Else**
 - *A* \leftarrow the attribute in *attributes* which best classifies *instances*
 - root decision attribute \leftarrow *A*
 - **For**each possible value *v_j* **of** *A*,
 - Add a new ramification below root, corresponding to the test *A* = *v_j*
 - Let *instances_{vj}* be the subset of instances with the value *v_j* for *A*
 - **If** *instances_{vj}* is empty then
 - Below this ramification, add a new leaf node with the most common value of *target_attribute* in *instances*.
 - **Else** below this ramification, add the subtree given by the recursion:
*ID3(*instances_{vj}*, *target_attribute*, *attributes* – { *A* })*
- **End**

Numerical Example 1

Consider the **weather dataset** in which we have to decide that whether the player should play golf or not on the basis of weather conditions (shown in figure).

Train a decision tree classifier (using ID3 algorithm) that classifies any new test case according to given weather conditions.

S. No.	Outlook	Temperature	Humidity	Windy	PlayTennis
1	Sunny	Hot	High	Weak	No
2	Sunny	Hot	High	Strong	No
3	Overcast	Hot	High	Weak	Yes
4	Rainy	Mild	High	Weak	Yes
5	Rainy	Cool	Normal	Weak	Yes
6	Rainy	Cool	Normal	Strong	No
7	Overcast	Cool	Normal	Strong	Yes
8	Sunny	Mild	High	Weak	No
9	Sunny	Cool	Normal	Weak	Yes
10	Rainy	Mild	Normal	Weak	Yes
11	Sunny	Mild	Normal	Strong	Yes
12	Overcast	Mild	High	Strong	Yes
13	Overcast	Hot	Normal	Weak	Yes
14	Rainy	Mild	High	Strong	No

Solution- Example 1

Compute Entropy of the entire dataset:

$$Entropy(S) = - \sum_{i=1}^n p_i \log_2(p_i)$$

Positive Examples = 9

Negative Examples = 5

Total= 14

$$Entropy(S) = -\frac{9}{9+5} \log_2 \left(\frac{9}{9+5} \right) - \frac{5}{9+5} \log_2 \left(\frac{5}{9+5} \right) = 0.940$$

Solution- Example 1 (Contd.)

- For each attribute: (let say Outlook)
 - Calculate Entropy of each values, i.e., ‘Sunny’, ‘Rainy’, ‘Overcast’

$$\text{Entropy}(\text{Outlook} = \text{Sunny}) = -\frac{2}{2+3} \log_2 \left(\frac{2}{2+3} \right) - \frac{3}{2+3} \log_2 \left(\frac{3}{2+3} \right) = 0.971$$

$$\text{Entropy}(\text{Outlook} = \text{Rainy}) = -\frac{3}{2+3} \log_2 \left(\frac{3}{2+3} \right) - \frac{2}{2+3} \log_2 \left(\frac{2}{2+3} \right) = 0.971$$

$$\text{Entropy}(\text{Outlook} = \text{Overcast}) = -\frac{4}{4+0} \log_2 \left(\frac{4}{4+0} \right) - \frac{0}{4+0} \log_2 \left(\frac{0}{4+0} \right) = 0$$

$$\text{Average Information Entropy} = \sum_{v=1}^{|V|} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$$

$$\text{Average Information Entropy} =$$

$$I(S, \text{Outlook}) = \frac{2+3}{9+5} \times 0.971 + \frac{3+2}{9+5} \times 0.971 + \frac{4+0}{9+5} \times 0 = 0.693$$

$$\text{Information Gain}(S, \text{Outlook}) = \text{Entropy}(S) - I(S, \text{Outlook})$$

$$= 0.940 - 0.693 = 0.247$$

Outlook	PlayTennis	Outlook	PlayTennis	Outlook	PlayTennis
Sunny	No	Rainy	Yes	Overcast	Yes
Sunny	No	Rainy	Yes	Overcast	Yes
Sunny	No	Rainy	No	Overcast	Yes
Sunny	Yes	Rainy	Yes	Overcast	Yes
Sunny	Yes	Rainy	No	Overcast	Yes

Outlook	p	n	Entropy
Sunny	2	3	0.971
Rainy	3	2	0.971
Overcast	4	0	0

Solution- Example 1 (Contd...)

- For each attribute: (let say Temperature)
 - Calculate Entropy of each values, i.e., 'Hot', 'Mild', 'Cool'

$$\text{Entropy}(\text{Temp} = \text{Hot}) = -\frac{2}{2+2} \log_2 \left(\frac{2}{2+2} \right) - \frac{2}{2+2} \log_2 \left(\frac{2}{2+2} \right) = 0$$

$$\text{Entropy}(\text{Temp} = \text{Mild}) = -\frac{4}{4+2} \log_2 \left(\frac{4}{4+2} \right) - \frac{2}{4+2} \log_2 \left(\frac{2}{4+2} \right) = 0.918$$

$$\text{Entropy}(\text{Temp} = \text{Cool}) = -\frac{3}{3+1} \log_2 \left(\frac{3}{3+1} \right) - \frac{1}{3+1} \log_2 \left(\frac{1}{3+1} \right) = 0.811$$

$$\text{Average Information Entropy} = \sum_{v=1}^{|V|} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$$

$$\text{Average Information Entropy} =$$

$$I(S, \text{Temp}) = \frac{2+2}{9+5} \times 1 + \frac{4+2}{9+5} \times 0.918 + \frac{3+1}{9+5} \times 0.811 = 0.911$$

$$\text{Information Gain}(S, \text{Temp}) = \text{Entropy}(S) - I(S, \text{Temp})$$

$$= 0.940 - 0.911 = 0.029$$

Solution- Example 1 (Contd...)

- For each attribute: (let say Humidity)

- Calculate Entropy of each values, i.e., 'High', 'Normal',

$$\text{Entropy}(\text{Humidity} = \text{High}) = -\frac{3}{3+4} \log_2 \left(\frac{3}{3+4} \right) - \frac{4}{3+4} \log_2 \left(\frac{4}{3+4} \right) = 0.985$$

$$\text{Entropy}(\text{Humidity} = \text{Normal}) = -\frac{6}{6+1} \log_2 \left(\frac{6}{6+1} \right) - \frac{1}{6+1} \log_2 \left(\frac{1}{6+1} \right) = 0.591$$

$$\text{Average Information Entropy} = \sum_{v=1}^{|V|} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$$

Average Information Entropy =

$$I(S, \text{Humidity}) = \frac{3+4}{9+5} \times 0.985 + \frac{6+1}{9+5} \times 0.591 = 0.788$$

Information Gain(S , Humidity)

= $\text{Entropy}(S) - I(S, \text{Humidity})$

$$= 0.940 - 0.788 = 0.152$$

Humidity	PlayTennis

High	Yes
High	No
High	Yes
High	No

Humidity	p	n	Entropy
High	3	4	0.985
Normal	6	1	0.591

Solution- Example 1 (Contd...)

- For each attribute: (let say Windy)

- Calculate Entropy of each values, i.e., 'Strong', 'Weak',

$$\text{Entropy}(\text{Windy} = \text{Strong}) = -\frac{3}{3+3} \log_2 \left(\frac{3}{3+3} \right) - \frac{3}{3+3} \log_2 \left(\frac{3}{3+3} \right) = 1$$

$$\text{Entropy}(\text{Windy} = \text{Weak}) = -\frac{6}{6+2} \log_2 \left(\frac{6}{6+2} \right) - \frac{2}{6+1} \log_2 \left(\frac{2}{6+2} \right) = 0.811$$

$$\text{Average Information Entropy} = \sum_{v=1}^{|v|} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$$

Average Information Entropy =

$$I(S, \text{Windy}) = \frac{3+3}{9+5} \times 1 + \frac{6+2}{9+5} \times 0.811 = 0.892$$

$$\begin{aligned} \text{Information Gain}(S, \text{Windy}) &= \text{Entropy}(S) - I(S, \text{Windy}) \\ &= 0.940 - 0.892 = 0.048 \end{aligned}$$

Since Information Gain for Outlook is max, therefore root is *Outlook*

Outlook	Temperature	Humidity	Windy	PlayTennis
Overcast	Hot	High	Weak	Yes
Overcast	Cool	Normal	Strong	Yes
Overcast	Mild	High	Strong	Yes
Overcast	Hot	Normal	Weak	Yes

Outlook is selected as the root note

```
graph TD; Outlook((Outlook)) -- sunny --> ?1((?)); Outlook -- overcast --> Yes[yes]; Outlook -- rain --> ?2((?)); ?1 --> further["further splitting necessary"]; ?2 --> further;
```

The diagram shows a decision tree starting with 'Outlook' at the root. It branches into three categories: 'sunny', 'overcast', and 'rain'. The 'sunny' branch leads to a question mark node. The 'overcast' branch leads to a rectangular node labeled 'yes'. The 'rain' branch leads to another question mark node. Arrows from the question mark nodes point to a box labeled 'further splitting necessary'. A yellow box contains the text 'Outlook = overcast contains only examples of class yes'.

further splitting necessary

**Outlook = overcast
contains only
examples of class yes**

Solution- Example 1 (Contd...)

- REPEAT THE SAME THING FOR SUB-TREES TILL WE GET THE TREE.

Outlook	Temperature	Humidity	Windy	PlayTennis

Limitations of ID3 Algorithm

1. ID3 can handle only categorical values and not continuous valued features.
2. ID3 cannot handle incomplete data.
3. ID3 algorithm is biased towards the feature which has large number of distinct values.
 - This is due to the reason that feature is chosen on the basis of Information gain which is the difference between Entropy of parent set and average information entropy of feature.
 - So, if a feature has large number of distinct values, then reduction in entropy would be large.

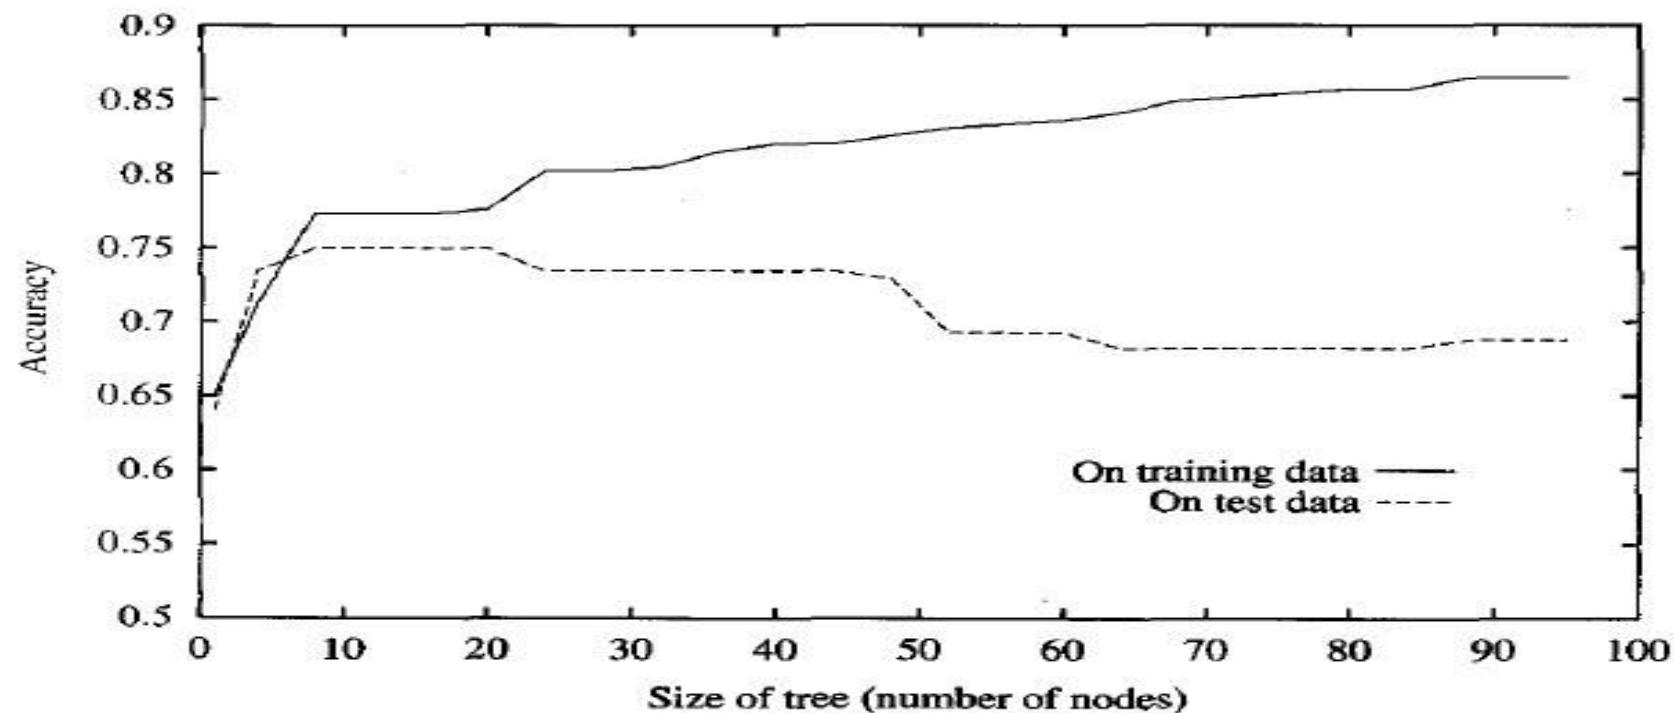

Limitations of ID3 Algorithm (Contd....)

4. Overfitting:

- ID3 algorithm grows each branch of the tree just deeply enough to perfectly classify the training examples.
- But it can lead to difficulties when there is noise in the data, or when the number of training examples is too small to produce a representative sample of the true target function.
- For example, consider a new instance in weather dataset, <Sunny, Hot, Normal, Strong, -> Example is noisy because the correct label is +.
- The addition of this incorrect example will now cause ID3 to construct a more complex tree.
- The result is that ID3 will output a decision tree (h) that is more complex than the original tree (h') which will perform quite well on training data but poor on test data.
- However, given that the new decision node is simply a consequence of fitting the noisy training example.

Limitations of ID3 Algorithm (Contd....)

The figure illustrates the impact of overfitting in a typical application of decision tree learning

Avoiding Overfitting

- There are several approaches to avoiding overfitting in decision tree learning. These can be grouped into two classes:
- **Pre-pruning (avoidance):**
 - Stop growing the tree earlier, before it reaches the point where it perfectly classifies the training data
- **Post-pruning (recovery):**
 - Allow the tree to overfit the data, and then post-prune the tree.
- Although the first of these approaches might seem more direct, the second approach of post-pruning overfit trees has been found to be more successful in practice.
- This is due to the difficulty in the first approach of estimating precisely when to stop growing the tree.
